INTERACTION OF BISOPROLOL OR ENALAPRIL WITH DISTEAROYL PHOSPHATIDYLCHOLINE LIPOSOMES: FTIR AND DSC STUDIES

M.W. SHAFAA

Physics Department, Medical Biophysics Division, Faculty of Science, Helwan University, Cairo, Egypt, e-mail: medhatwi@hotmail.com

Abstract. Using two non-invasive techniques of Fourier transform infrared (FTIR) spectroscopy and differential scanning calorimetry (DSC), the biophysical interactions of bisoprolol or enalapril with distearoyl phosphatidylcholine (DSPC) multilamellar liposomes were investigated. DSC analysis showed that the mixtures of DSPC and bisoprolol or enalapril show a single peak, which indicates that they are miscible. The encapsulated bisoprolol or enalapril is probably associated with the lipid bilayers that perturbed them which results in the strong broadening and shift to lower temperature 69 °C and 61 °C, respectively of the main characteristic endothermic peak of pure DSPC that exists at 102 °C. The pretransition of liposomes has disappeared for all samples containing bisoprolol or enalapril. Analysis of C=O stretching bond in FTIR spectroscopy showed that bisoprolol or enalapril does not make any hydrogen bonds with the interfacial region of DSPC liposomes, it induces free carbonyl groups in the system. These results revealed that enalapril or bisoprolol was located in the interfacial region of the membrane. The studies with model membranes could provide a rational approach for drug discovery.

Key words: DSPC liposomes, bisoprolol, enalapril, DSC, FTIR.

INTRODUCTION

Hypertension is simply defined as abnormally high blood pressure and especially arterial blood pressure. High blood pressure is a common condition in which the long-term force of the blood against artery walls is high enough that it may eventually cause health problems, such as heart disease. Arterial hypertension is a major cause of morbidity and mortality because of its association with coronary heart disease, cerebro-vascular disease and renal disease.

Bisoprolol hemifumarate belongs to the group of medicines referred to as beta-blockers used for the management of hypertension and angina pectoris. It is a medicine which works on the heart and blood vessels. It does this by blocking tiny

ROMANIAN J. BIOPHYS., Vol. 28, No. 3, P. 103-114, BUCHAREST, 2018

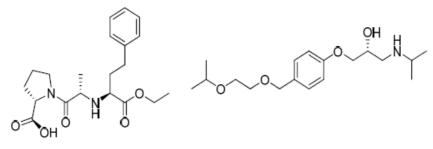

areas (called beta-adrenergic receptors) where messages sent by some nerves are received by heart and blood vessels. As a result, heart beats more slowly and with less force. The pressure of blood within blood vessels is reduced and it is easier for heart to pump blood around body resulting in decrease of arterial hypertension [8, 12].

Enalapril is a pro-drug, an ethyl ester of a long-acting inhibitor of angiotensinconverting enzyme (ACE), enalaprilat. After its oral absorption, enalapril is metabolized for hydrolysis by liver yielding enalaprilat [4]. This drug is indicated for the treatment of essential and renovascular hypertension and congestive heart failure [7]. The main mechanism responsible for the antihypertensive effect of the ACE inhibitors is the reduction in the circulating angiotensin II concentration.

Liposomes are widely accepted as a simplified model system of well-defined lipid molecules for the study of biomembranes. Biophysical interaction studies with model membrane could provide a simple yet effective approach to understanding the role of membrane lipids in the transport of drugs and drug delivery systems across biological barriers.

To our knowledge, there were no previous studies on the interaction of bisoprolol or enalapril with phospholipids from the perspective of the thermotropic phase behavior of phospholipids and to observe the changes of acyl chain conformations and characteristic PO_2^- bands in the polar heads of phospholipids. There have been no systematic investigations in relation to bisoprolol or enalapril and phospholipids using differential scanning calorimetry (DSC) and Fourier transform infrared (FTIR) spectroscopy. These two techniques are highly effective in probing the interaction between drugs and phospholipids [14].

The main aim of this work is to investigate the impact of bisoprolol or enalapril as antihypertensive drugs on the structural properties of model lipid membranes and to estimate the subtle perturbation of the lipid bilayer structure using two noninvasive techniques such DSC and FTIR. The structures of enalapril and bisoprolol are presented in Fig. 1.

Enalapril

Bisoprolol

Fig. 1. Schematic chemical structure of enalapril and bisoprolol.

MATERIALS AND METHODS

CHEMICALS

1,2-Distearoyl-sn-glycero-3-phosphocholine (DSPC) in powder form and of purity 99%, presented in Fig. 2, with a molecular weight of 790.145, was purchased from Lipoid KG, Ludwigshafen, Germany, Trizma buffer, molecular weight of 121.1 was purchased from Sigma chemicals, Steinheim, Germany. Ethanol was of analytical grade and obtained from Merck, Heliopolis, Cairo, Egypt [3]. Bisoprolol and enalapril, with a molecular weight of 325.443 and 376.447 respectively, were purchased from EIPICO, Egypt. All other reagents and solvents used in this work were of research grade.

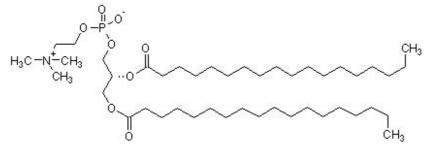

Fig. 2. Schematic chemical structure of DSPC.

PREPARATION OF BISOPROLOL OR ENALAPRIL- DOPED LIPOSOMES

A molar ratio 7:2 of DSPC to bisoprolol or enalapril was used to prepare neutral liposomal multilamellar vesicles (MLVs) using the method of Deamer and Uster [2]. In round bottom flask of capacity 50 mL, 20 mg of DSPC and 2.4 mg bisoprolol or 2.72 mg enalapril of the drug powder at molar ratio 7:2 were mixed. Then 10 mL of ethanol (EtOH) was added, and the flask was shaken until all lipids dissolved in the EtOH. The solvent was evaporated under vacuum using a rotary evaporator until a thin dry film of lipid was formed. Then 10 mL of buffer (10 mM Trizma at pH = 7) was then added to the flask which was flashed through with nitrogen stream and immediately stoppered. The flask is mechanically shaken for 1 h at a temperature above the phase transition temperature of lipids (45 °C). The suspension was then centrifuged at 8000 rpm for 20 min and the supernatant was discarded. The liposomes were then re-suspended in 10 mL buffer solution. Control liposomes were prepared using only 20 mg of DSPC.

ENCAPSULATION EFFICIENCY MEASUREMENTS

The encapsulation efficiency (EE) of bisoprolol or enalapril encapsulated into liposomes was determined using a spectrophotometer (Uvikon 930, Italy). The

M.W. Shafaa	
-------------	--

wavelengths were adjusted at 275 nm and 209 nm, the resonance absorption peaks of bisoprolol and enalapril respectively. The absorption of the supernatant of each sample was compared with the standard curve that relates absorption to the concentration of bisoprolol or enalapril. Encapsulation efficiency (*EE*) was calculated from the following formula:

$$EE = \frac{Total \, drug \, input \, (mg) - Drug \, in \, supernatant \, (mg)}{Total \, drug \, input \, (mg)} \times 100 \tag{1}$$

DSC MEASUREMENTS

Differential scanning calorimetry (DSC) experiments were carried out using (model TA-50 WSI, Schimadzu, Japan) calibrated with indium to investigate the thermal behavior of lyophilized samples of empty and bisoprolol or enalapril-doped multilamellar liposomes. The analyses were performed on 5 mg samples sealed in standard aluminum pans. The thermogram of each sample covered the 20-200 °C temperature range at a scanning rate of 5 °C/min [10].

FTIR SPECTROSCOPY

FTIR spectra of lyophilized samples of empty DSPC liposomes and DSPC liposomes encapsulated bisoprolol or enalapril deposited in KBr disks were recorded on a NICOLET 6700 FTIR spectrometer (Thermo Scientific, Cambridge, England). Scanning was carried out at room temperature, in the range 400–4,000 cm⁻¹ at a speed of 2 mm/s and a resolution of 4 cm⁻¹.

RESULTS AND DISCUSSION

The entrapment efficiency was found higher than 90% when mixing the drug with the lipid powder before dissolving it in ethanol.

DSC is a fundamental technique for the characterization of membrane behavior, providing all thermodynamic parameters for temperature-induced transitions. The phase transition temperatures studied by DSC can give an idea about the different mechanisms that occur in the liposomal membrane as a model of the biological membrane system.

The most ubiquitous of these is the gel-to-liquid crystalline transition, often referred to as the melting or main transition. This transition is relatively rapid and is highly reversible. It is characterized by the co-operative melting of the hydrocarbon chains and a high enthalpy DSC peak. The liquid crystalline ($L\alpha$) phase has an increased number of gauche conformers and a large increase in membrane fluidity and disorder [13]. The pre-transition from the planar gel ($L\beta'$) to the rippled gel

phase $(P\beta')$ has a low enthalpy and is sensitive to sample preparation and the presence of impurities [5]. All of the above phases are strongly affected by changes in lipid structure.

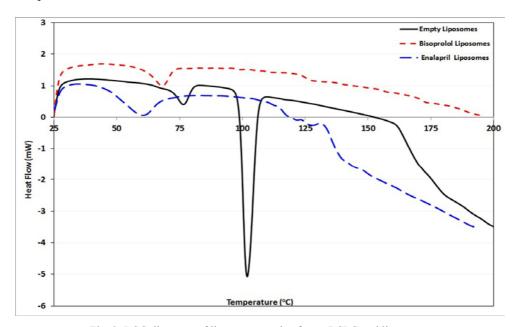

Fig. 3. DSC diagrams of liposomes made of pure DSPC and liposomes doped with bisoprolol or enalapril.

The temperature at which a transition from the gel phase to the rippled phase takes place is called the pre-transition temperature and it is mainly related to the polar region of phospholipids. Subsequently, the melting of the bilayer from the rippled phase to the liquid phase occurs at the main transition temperature (T_m) . The melting point (T_m) represents the peak temperature of the endotherm for the lipid gel-to fluid phase transition recorded during the heating scan.

The DSPC vesicles were used as model membranes since this phospholipid can mimic many aspects of biological membranes. Pure DSPC vesicles upon dehydration, when submitted to DSC analysis, showed a major endothermic peak at 102 °C (Fig. 3), in accordance with [5, 10, 11]. The pre-transition temperature was around 80 °C for pure DSPC liposomes.

The presence of a compound in the DSPC membranes could influence the thermotropic parameters of the vesicle transition. The incorporation of bisoprolol or enalapril into DSPC liposomes exhibited a noticeable shift to lower temperature at 69 °C and 61 °C, respectively, in comparison to the main endothermic peak of empty DSPC, that exists at 102 °C, which suggests that bisoprolol or enalapril had a significant effect on the acyl chains of DSPC bilayers, creating a conformational

disorder within the acyl chains of phospholipids and decreased cooperatively the transition of lipid acyl chains. The lowered temperature of the main DSPC transition process indicated that the incorporation of bisoprolol or enalapril is more favorable to the formation of acyl chains in a disordered and loose state. The pre-transition temperature peak for bisoprolol or enalapril liposomes has disappeared, which revealed that bisoprolol or enalapril interacted with the polar head group of phospholipids. The disappearance of the pre-transition is sensitive for the incorporation of biomolecules into lipid bilayers.

Upon the incorporation into DSPC liposomes, the pronounced effect of bisoprolol or enalapril was observed in comparison with pure DSPC liposomes. The incorporated bisoprolol or enalapril is probably associated and interacted to a large extent with the lipid bilayers that perturbed them which results in the broadening of the main characteristic endothermic peak of pure DSPC that exists at 102 °C. It has been observed using DSC that the mixtures of DSPC and bisoprolol or enalapril show a single peak, which indicates that they are miscible.

FTIR spectroscopy is a technique which can provide a quantitative chemical composition and identify tissue constituents. FTIR spectroscopy was used to monitor subtle changes in the structure and function of the lipid assemblies by analyzing the frequency and bandwidth changes of different vibrational modes representing the acyl chains, interfacial, and head group region of lipid molecules.

The measuring of some spectral parameters like band frequency, width and intensity change provided information regarding the possible structural interactions and conformational rearrangements taking place.

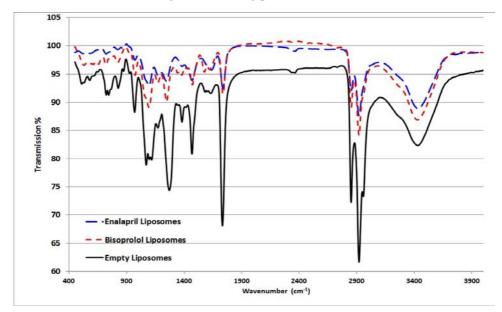

Fig. 4. The full FTIR spectra of empty DSPC and DSPC / bisoprolol or enalapril liposomal samples.

FTIR spectra of pure lyophilized DSPC liposomes compared with enalapril or bisoprolol/DSPC liposomal sample in the region 4000–400 cm⁻¹ are presented in Fig. 4. The spectrum of the DSPC liposomes displayed the main characteristic bands, especially those which are due to the symmetric and antisymmetric $PO_2^$ stretching vibrations at 1090 and 1220 cm⁻¹, respectively, the CH₂ bending vibration CH₂ near 1470 cm⁻¹, the carbonyl stretching vibration C=O at 1734 cm⁻¹, the OH stretching and bending vibrations at 3470 and 1640 cm⁻¹, respectively and the symmetric and antisymmetric stretching vibrations of the CH₂ in the acyl chain around 2850 and 2920 cm⁻¹, respectively. These findings are in good accordance with the data reported in the literature [6].

The detailed spectral analyses were performed in three distinct wave number regions, namely $3500-2800 \text{ cm}^{-1}$, $1800-1500 \text{ cm}^{-1}$ and $1500-400 \text{ cm}^{-1}$, since identifiable Raman bands were observed mainly in these regions only.

Lipids give rise to a number of absorptions in Raman spectra. The most intense of these absorptions are found in the $3500-2800 \text{ cm}^{-1}$ region, attributed to asymmetric and symmetric stretching vibrations of CH₃ and CH₂ groups of acyl chains. The most intense band observed at 3500 cm^{-1} in the control and treated samples has been assigned as presence of hydroxyl compound.

Encapsulation of bisoprolol into the DSPC liposomes exhibited a slight change in the frequency of the symmetric CH_2 stretching bands in the acyl chain appeared in Fig. 5, suggesting that bisoprolol created a conformational disorder within the acyl chains of phospholipids. In other words, it influenced the order of the membrane. For enalapril /DSPC FTIR spectrum, there was no significant change in the frequency of the CH_2 stretching bands observed in Fig. 5, suggesting that enalapril does not change the number of gauche conformers. In other words, it did not have any significant effect on the order of the membrane.

The interaction between enalapril/bisoprolol and the head group of DSPC liposomes was monitored by means of the PO_2^- symmetric stretching band, which is located at 1092 cm⁻¹. Figure 6 shows the PO_2^- symmetric stretching band for DSPC liposomes formulations in the absence and presence of enalapril and bisoprolol. A decrease in the frequency corresponds to the hydrated phosphate group. The frequency of this band determines the presence of hydrogen bonding between phosphate group and hydrogen atoms of water or biological macromolecules. As can be seen from Fig. 6, the wavenumber was shifted towards higher degrees (1095 cm⁻¹ and 1094 cm⁻¹) after the incorporation of enalapril or bisoprolol into DSPC lipo-somes, respectively. This implied the absence of hydrogen bonding between the liposome head group and enalapril/bisoprolol. In accordance with the empirical rules, decreasing frequency values display an increase in the strengthening of existing hydrogen bonding or in the formation of new hydrogen bonding between the components [9].

The PO_2^{-} antisymmetric stretching band, which is located at 1222 cm⁻¹ for DSPC liposomes, was significantly increased after the encapsulation of enalapril or bisoprolol into DSPC liposomes. This implied the absence of hydrogen bonding between the liposome head group and enalapril/bisoprolol. These results implied that enalapril or bisoprolol was located in the interfacial region of the membrane.

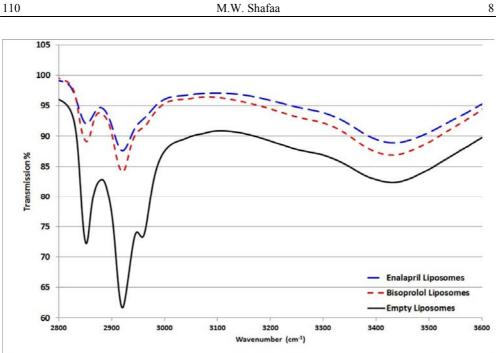

Fig. 5. The magnified part (3500–2800 cm⁻¹) of FTIR spectra of empty DSPC and DSPC / bisoprolol or enalapril liposomal samples.

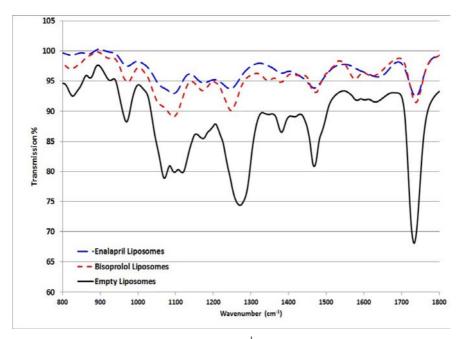

Fig. 6. The magnified part (1800-800 cm⁻¹) of FTIR spectra of empty DSPC and DSPC/ bisoprolol or enalapril liposomal samples.

The interesting finding that can be concluded from Fig. 6 is that the CH_2 bending vibration mode which is located at 1467 cm⁻¹ is affected by the incorporation of enalapril or bisoprolol into DSPC liposomal preparation. The wavenumber was shifted towards higher values (1468 cm⁻¹ and 1471 cm⁻¹) after the encapsulation of enalapril or bisoprolol into DSPC liposomes, respectively. This might assume that the molecules of enalapril and bisoprolol act as small spacers of the polar head group, leading to a slight disorder in the hydrocarbon chains.

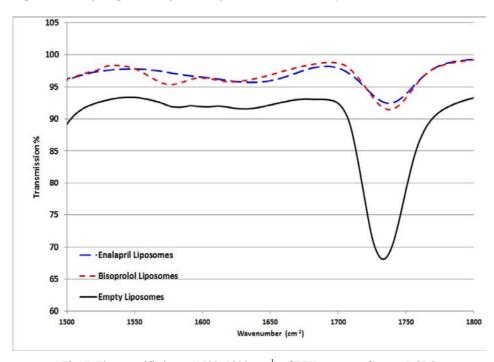

Fig. 7. The magnified part (1500–1800 cm⁻¹) of FTIR spectra of empty DSPC and DSPC / bisoprolol or enalapril liposomal samples.

Concerning the interaction of enalapril/bisoprolol with glycerol backbone near the head group of phospholipids in interfacial region, the C=O stretching band was analyzed. The wavenumber variation of this band is shown in Fig. 7. As seen from Figure 7, the wavenumber value of C=O group was shifted to higher frequencies (from 1732 cm⁻¹ to 1737 cm⁻¹) for the liposomes sample containing enalapril and bisoprolol respectively, without any evidence of hydrogen bonding formation. The absorption bands of ester C=O are sensitive to changes in the polarity of their local environments and are influenced by hydrogen bonding and other interactions. Therefore, changes in the contours of the ester C=O absorption band can often be interpreted in terms of structural and/or hydration changes of the bilayer polar/ apolar interface [1]. The wavenumber value of C=O group exhibited a shift towards higher frequency (from 1732 cm^{-1} to 1737 cm^{-1}) for the liposomes sample containing bisoprolol or enalapril, implying dehydration about these functional groups in the interfacial region of the lipid membranes. Therefore, any effects in the spectra of this region can be attributed to an interaction between Enalapril/ bisoprolol and the polar/apolar interfacial region of the membrane. Enalapril/ bisoprolol tends to reduce the forming of hydrogen bonding in the interfacial region of DSPC liposome, implying the existing of the free carbonyl groups in the system. Some H₂O molecules are probably replaced by bisoprolol or enalapril from the interfacial region and lead to an increase in the number of free carbonyl groups.

Also, the N(CH₃)₃⁺ antisymmetric stretching band at 970 cm⁻¹ is increased for enalapril or bisoprolol/DSPC liposomal sample (Table 1). The existence of a N(CH₃)₃⁺ group in the polar head of DSPC might prevent the enalapril or bisoprolol NH group from getting close to the PO₂⁻ group, because of the electrostatic repulsive force between the DSPC N(CH₃)₃⁺ group and the enalapril or bisoprolol NH group; thus, weakening the interactions between phospholipid PO₂⁻ and enalapril or bisoprolol NH group. Table 1 summarizes the chemical shift observed for enalapril or bisoprolol after the incorporation into DSPC liposomes.

Dools assignment	Wave number	Wave number (cm^{-1})		
Peak assignment	(cm^{-1})	Control	Bisoprolol	Enalapril
Symmetric stretching vibration of CH ₂ in acyl chain	2850 (2800–2855)	2852.203	2853.167	2852.203

(CH ₃) ₃ N ⁺ antisymmetric	972	970.0189	972.9116	971.9473

Table 1 The chemical shift observed for enalapril or bisoprolol after the incorporation into DSPC liposomes

CONCLUSION

The molecular interaction of enalapril or bisoprolol as antihypertensive drugs with DSPC was investigated using two non-invasive techniques FTIR and DSC. Based on these results, we propose that enalapril or bisoprolol can be interacted actively with the lipids and induce changes in their physical-chemical properties, thus affecting its IR spectra, thermotropic phase behavior and membrane fluidity. In addition, a possible location of enalapril or bisoprolol in the interfacial region of the membrane has been proposed. These findings facilitate a better understanding of the interactions between enalapril or bisoprolol as antihypertensive drugs and lipid bilayers.

Acknowledgements. We thank Mohamed Nabil and Ismail Mohamed for their valuable technical assistance.
